SOME TESTS CONCERNING THE COVARIANCE MATRIX IN HIGH DIMENSIONAL DATA

Muni S. Srivastava*

In this paper, tests are developed for testing certain hypotheses on the covariance matrix Σ, when the sample size \( N = n + 1 \) is smaller than the dimension \( p \) of the data. Under the condition that \( (\text{tr} \Sigma^i/p) \) exists and > 0, as \( p \to \infty \), tests are developed for testing the hypotheses that the covariance matrix in a normally distributed data is an identity matrix, a constant time the identity matrix (sphericity), and is a diagonal matrix. The asymptotic null and non-null distributions of these test statistics are given.

**Key words and phrases:** Asymptotic distributions, multivariate normal, null and non-null distributions, sample size smaller than the dimension.

1. Introduction

Recent advances in analyzing high dimensional data with fewer observations require that certain assumptions made implicitly or explicitly in analyzing them should be ascertained. For example, Dudoit et al. (2002) in their analysis of microarrays data on genes assume that the covariance matrices are diagonal matrices, and thus their distance function uses only the diagonal elements of the sample covariance matrix. The good performance of their procedures appear to suggest that this indeed might be the case. To ascertain these assumptions on the covariance matrix, the likelihood ratio tests cannot be used as the sample size \( N = n + 1 \) could be smaller than the dimension \( p \). Although, the locally best invariant (LBI) test proposed by John (1971) and considered by Suguira (1972), and Nagao (1973) for the sphericity hypothesis and the LBI test given by Nagao (1973) for testing the hypothesis that the covariance matrix Σ is an identity matrix can be computed for all sample sizes, there appears to be no theoretical justification for using them as LBI tests cannot be obtained when \( n < p \). Thus, we consider a distance function between the null hypothesis and the alternative hypothesis, and propose tests based on consistent estimators of these parametric functions of the covariance matrix Σ for testing the hypothesis of sphericity of the covarianace matrix, and for testing the hypothesis that the covarianace matrix is an identity matrix. In addition, under the same set of conditions, we provide tests for testing the hypothesis that the covarianace matrix is a diagonal matrix. Asymptotic distributions of these test statistics are given under the hypothesis as well as under the alternative hypothesis. Our focus is however for the case when \( n = O(p^\delta), 0 < \delta \leq 1 \). Thus, it includes the case when \( (n/p) \to 0 \).
organization of the paper is as follows.

In Section 2, we present notations and some preliminary results. Sections 3 to 5 develop tests for testing that the covariance matrix $\Sigma = \sigma^2 I$, $\Sigma = I_p$, and $\Sigma = \text{diag}(\sigma_{11}, \ldots, \sigma_{pp})$ respectively. The proofs of theorems and lemmas stated in Sections 2 to 4 are given in Section 6.

2. Notations and preliminaries

Let $x_1, \ldots, x_N$ be independently and identically distributed (iid) as a $p$-dimensional random vector $x$ which is distributed as multivariate normal with mean vector $\mu$ and covariance matrix $\Sigma$, denoted, $x \sim \mathcal{N}_p(\mu, \Sigma)$. We shall assume that $\Sigma > 0$, that is, it is a positive definite matrix. Let $\overline{x}$ and $S$ denote the sample mean vector and the sample covariance matrix respectively, defined as

\begin{equation}
\overline{x} = N^{-1} \sum_{\alpha=1}^{N} x_{\alpha}, \quad N = n + 1,
\end{equation}

and

\begin{equation}
S \equiv n^{-1} V = n^{-1} \sum_{\alpha=1}^{N} (x_{\alpha} - \overline{x})(x_{\alpha} - \overline{x})',
\end{equation}

respectively. Let

\[ a_i = (\text{tr } \Sigma^i / p), \quad i = 1, \ldots, 8. \]

We make the following assumptions:

(A) : As $p \to \infty$, $a_i \to a_i^0$, $0 < a_i^0 < \infty$, $i = 1, \ldots, 8.$

(B) : $n = O(p^\delta)$, $0 < \delta \leq 1$.

In the next lemma, we give unbiased and consistent estimators of $a_1$ and $a_2$.

**Lemma 2.1.** Under the assumption (A), and as $n \to \infty$, an unbiased and consistent estimators of $a_1$ and $a_2$ are respectively given by

\begin{align*}
\hat{a}_1 &= (\text{tr } S) / p, \\
\hat{a}_2 &= \frac{n^2}{(n-1)(n+2)} \frac{1}{p} \left[ \text{tr } S^2 - \frac{1}{n} (\text{tr } S)^2 \right].
\end{align*}

For proof, see Section 6.

**Theorem 2.1.** Let $\hat{a}_1$ and $\hat{a}_2$ be as defined in (2.3) and (2.4) respectively. Then under the assumption (A), asymptotically

\begin{equation}
\left( \frac{\hat{a}_1}{\hat{a}_2} \right) \sim N_2 \left[ \begin{pmatrix} a_1 \\ a_2 \end{pmatrix}, (np)^{-1} \begin{pmatrix} 2a_2 & 4a_3 \\ 4a_3 & 8a_4 + 4(p/n)a_2^2 \end{pmatrix} \right].
\end{equation}
The proof is given in Section 6.

Remark 2.1. From the definition of \( \hat{a}_1 \) and \( \hat{a}_2 \), it follows that

\[
\left( \frac{\text{tr}S^2}{p} \right) = \hat{a}_2 + \frac{1}{pn}(\text{tr} S)^2 = \hat{a}_2 + \frac{p}{n} \hat{a}_1^2.
\]

Thus, unless \((p/n)\) goes to zero as \(n \to \infty\), \((\text{tr} S^2/p)\) is not a consistent estimator of \(a_2\). That is, if \(n = O(p)\), \((\text{tr} S^2/p)\) is not a consistent estimator of \((\text{tr} \Sigma^2/p)\), while \(\hat{a}_2\) is always a consistent estimator of \(a_2\) irrespective of how \(n \to \infty\), provided the assumption (A) is satisfied.

Corollary 2.1. Let \(n\) and \(p \to \infty\) such that \((p/n) \to c\). Then, asymptotically

\[
\left( \frac{p^{-1}(\text{tr} S)}{p^{-1}(\text{tr} S^2)} \right) \sim N_2 \left( \begin{pmatrix} a_1 \\ a_2 + ca_1^2 \end{pmatrix}, n^{-2}c^{-1}\Delta \right),
\]

where

\[
\Delta = \begin{pmatrix} 2a_2 & 4(ca_1a_2 + a_3) \\ 4(ca_1a_2 + a_3) & 4(2a_4 + ca_2^2 + 4ca_1a_3 + 2c^2a_1^2a_2) \end{pmatrix}.
\]

The proof is given in Section 6.

Let \(A = (a_1, \ldots, a_q) : p \times q\). Then \(\text{vec}(A)\) is a \(pq \times 1\) vector defined by \(\text{vec}(A) = (a_1', \ldots, a_q')\). Now, we consider some known asymptotic results.

Lemma 2.2. \(nS = n(s_{ij}) \sim W_p(\Sigma, n)\), where \(\Sigma = (\sigma_{ij})\). Then, if \(\theta = \text{vec}(\Sigma)\) and \(B = (b_{ij})\),

\[
\text{vec}(B) \equiv \sqrt{n}(\text{vec}(S) - \theta) \text{ is } AN_{p^2}(0, \Omega),
\]

where the elements of \(\Omega\) are given by

\[
E(b_{ij}b_{kl}) = \sigma_{ik}\sigma_{jl} + \sigma_{il}\sigma_{jk},
\]

see Hsu (1949), Bilodeau and Brenner (1999, p. 79–80) or Srivastava and Khatri (1979, Problem 3.32, p. 103).

Lemma 2.3. Let \(g = (g_1, \ldots, g_k)'\), where \(g_i's\) are differentiable functions of \(\text{vec} S : p^2 \times 1\) at \(\theta = \text{vec} \Sigma\). Then

\[
\sqrt{n}(g(\text{vec}(S)) - g(\theta)) \to N_k(0, Dg(\theta)\Omega(Dg(\theta))'),
\]

where

\[
Dg(\theta) = \left( \frac{\partial g}{\partial \text{vec}(S)'} \right)_{\text{vec}S=\theta} : k \times p^2.
\]

For proof, see Bilodeau and Brenner (1999, p. 79).
3. A test for the sphericity

In this section, we consider the problem of testing the hypothesis

\[ H : \Sigma = \sigma^2 I \quad \text{vs} \quad A : \Sigma \neq \sigma^2 I, \]

when a sample of size \( N = n + 1, x_1, \ldots, x_N \) is drawn from \( N_p(\mu, \Sigma) \). When \( n > p \), the most appropriate commonly used test statistic is the likelihood ratio test which has been shown by Carter and Srivastava (1977) to have a monotone power function. However, when \( n < p \) the likelihood ratio test is not available. Even the competitive locally best invariant test which can be calculated for \( n < p \), cannot be justified on theoretical grounds, although Ledoit and Wolf (2002) have proposed this LBI test and have given its asymptotic distribution when \( (p/n) \to c \), a constant, but the non-null distribution is not available. In this paper, we consider a test based on a consistent estimator of a parametric function of \( \Sigma \) which separates the null hypothesis from the alternative hypothesis which we discuss next.

The testing problem remains invariant under the transformation \( x \to Gx \), where \( G \) belongs to the group of orthogonal matrices. The problem also remains invariant under the scalar transformation \( x \to cx \). Thus, we may assume without any loss of generality that \( \Sigma = \text{diag}(\lambda_1, \ldots, \lambda_p) \), a \( p \times p \) diagonal matrix. From the Cauchy-Schwarz inequality, it follows that

\[
\left( \sum_{i=1}^{p} \lambda_i \times 1 \right)^2 \leq p \left( \sum \lambda_i^2 \right)
\]

with equality holding if and only if \( \lambda_i \equiv \lambda \) for some constant \( \lambda \). Thus

\[
\gamma_1 \equiv \frac{(\sum_{i=1}^{p} \lambda_i^2/p)}{(\sum_{i=1}^{p} \lambda_i/p)^2} \geq 1,
\]

and is equal to one if and only if \( \lambda_i = \lambda \) for some constant \( \lambda \). Thus, \( \gamma_1 \) is equal to one if and only if \( \lambda_i = \lambda \) for some constant \( \lambda \). Hence, we may consider testing the hypothesis

\[ H : \gamma_1 - 1 = 0 \quad \text{vs} \quad A : \gamma_1 - 1 > 0. \]

A test for the above hypothesis \( H \) vs \( A \) can be based on a consistent estimator of \( \gamma_1 \).

From Lemma 2.1, it follows that under the assumptions (A) and (B), a consistent estimator of \( \gamma_1 \) is given by

\[
\hat{\gamma}_1 = \frac{n^2}{(n-1)(n+2)} \frac{1}{P} \left[ \text{tr} S^2 - \frac{1}{n} (\text{tr} S)^2 \right] / (\text{tr} S/p)^2 = \frac{\hat{a}_2}{\hat{a}_1^2}.
\]

Thus, a test for the sphericity can be based on the statistic

\[ T_1 = \hat{\gamma}_1 - 1. \]
The following theorem gives the asymptotic non-null distribution of the statistic $T_1$.

**Theorem 3.1.** Under the assumptions (A) and (B), asymptotically

\[
\left(\frac{n}{2}\right) (T_1 - \gamma_1 + 1) \sim N(0, \tau_1^2)
\]

where

\[
\tau_1^2 = \frac{2n(a_4a_1^2 - 2a_1a_2a_3 + a_3^2)}{pa_1^6} + \frac{a_2^2}{a_1^4}.
\]

**Corollary 3.1.** Under the hypothesis that $\gamma_1 = 1$, and under the assumptions (A) and (B), asymptotically

\[
\frac{n}{2} T_1 \sim N(0, 1).
\]

**Remark 3.1.** The reader is reminded that it is a one-sided test for testing the hypothesis that $\gamma_1 = 1$ vs $\gamma_1 > 1$.

4. **A test for the covariance matrix to be an identity matrix**

Let $x_1, \ldots, x_N$ be iid $N_p(\mu, \Sigma)$. In this section, we consider the problem of testing the hypothesis $H : \Sigma = I$ against the alternative $A : \Sigma \neq I$.

The usual likelihood ratio test for $n > p$ which has monotone power function as shown by Nagao (1967) does not exist when $n < p$. Even, the locally best invariant test proposed by Nagao (1973) cannot be justified theoretically. However, Ledoit and Wolf (2002) have porposed a modified version of Nagao’s test and have given its asymptotic null distribution when $(p/n) \to c > 0$, where $c$ is a constant but the non-null distribution is lacking. In this paper, we consider a distance function between the hypothesis and the alternative hypothesis and propose a test based on a consistent estimator of this parametric function, which we discuss next. Since the problem remains invariant under the group of orthogonal transformations, we may assume without any loss of generality that $\Sigma = \text{diag}(\lambda_1, \ldots, \lambda_p)$, a diagonal matrix and test the hypothesis that $\lambda_i = 1$, $i = 1, \ldots, p$ against the alternative that $\lambda_i \neq 1$, for at least one $i$, $i = 1, \ldots, p$. But $\lambda_i = 1$ for all $i$ if and only if

\[
\frac{1}{p} \Sigma_{i=1}^p (\lambda_i - 1)^2 = 0.
\]

That is,

\[
\frac{1}{p} \left[ \sum \lambda_i^2 - 2 \sum \lambda_i + p \right] = \frac{1}{p} \left[ \text{tr} \Sigma^2 - 2 \text{tr} \Sigma + p \right] = a_2 - 2a_1 + 1 = 0.
\]
Thus, a test for the hypothesis \( H : \Sigma = I \) vs \( A : \Sigma \neq I \), can be based on a consistent estimator of

\[
\gamma_2 = a_2 - 2a_1.
\]

From Lemma 2.1, it follows that under the assumptions (A) and (B), an unbiased and consistent estimate of \( \gamma_2 \) is given by

\[
\hat{\gamma}_2 = \frac{n^2}{p(n-1)(n+2)} \left[ \text{tr } S^2 - \frac{1}{n} (\text{tr } S)^2 \right] - \frac{2}{p} [\text{tr } S]
\]

and our test will be based on the test statistic

\[
T_2 = \hat{\gamma}_2 + 1.
\]

**Theorem 4.1.** Under the assumptions (A) and (B), asymptotically

\[
\left( \frac{n}{2} \right) (T_2 - \gamma_2 - 1) \sim N(0, \tau^2_2),
\]

where

\[
\tau^2_2 = \frac{2n}{p} (a_2 - 2a_3 + a_4) + a_2^2.
\]

The proof is given in Section 6.

**Corollary 4.1.** Under the hypothesis \( H : \Sigma = I \), and the assumptions (A) and (B), the asymptotic null distribution of \( T_2 \) is given by

\[
\left( \frac{n}{2} \right) T_2 \rightarrow N(0, 1).
\]

**Remark 4.1.** This is a one-sided test for testing \( H : \gamma_2 + 1 = 0 \) vs \( A : \gamma_2 + 1 > 0 \).

**Remark 4.2.** For testing the hypothesis that \( \Sigma = \Sigma_0 \), we consider the observations \( y_i = \Sigma_0^{1/2} x_i \), and test the hypothesis that the covariance matrix of \( y_i \) is an identity matrix. Here \( \Sigma = (\Sigma^{1/2})(\Sigma^{1/2}) \).

**5. A test for the covariance to be diagonal**

Let \( x_1, \ldots, x_N \) be iid \( N_p(\mu, \Sigma) \). We wish to test the hypothesis \( H : \sigma_{ij} = 0 \), \( i \neq j \), \( i, j = 1, \ldots, p \), against the alternative \( A : \sigma_{ij} \neq 0 \), for at least one pair \( (i, j) \), \( i \neq j \), where \( \Sigma = (\sigma_{ij}) \). Without loss of generality, we may consider the hypothesis \( H : \rho_{ij} = 0 \) vs \( A : \rho_{ij} \neq 0 \) for at least one pair \( (i, j) \), \( i \neq j \),
SOME TESTS CONCERNING COVARIANCE MATRIX 257

$i, j = 1, \ldots, p$ where $\rho_{ij} = \sigma_{ij}/(\sigma_{ii}\sigma_{jj})^{1/2}, i \neq j$. Let $r_{ij}$ be the sample correlation coefficient defined by

$$r_{ij} = \frac{s_{ij}}{\sqrt{s_{ii}s_{jj}}} = \frac{v_{ij}}{\sqrt{v_{ii}v_{jj}}}, \quad i \neq j, \ i, j = 1, \ldots, p. \tag{5.1}$$

where $S = (s_{ij})$ and $nS = V = (v_{ij})$. Define

$$q = \frac{1}{2}p(p-1), \quad r = (r_{12}, r_{13}, \ldots, r_{p-1,p})', \tag{5.2}$$

and

$$\rho = (\rho_{12}, \rho_{13}, \ldots, \rho_{p-1,p})'. \tag{5.3}$$

Then it follows from the results of Hsu (1949), that as $n \to \infty$,

$$\sqrt{n}(r - \rho) \to N_q(0, \Omega),$$

where the diagonal elements of $\Omega$ are given by $(1 - \rho_{12}^2)^2, (1 - \rho_{13}^2)^2, \ldots, (1 - \rho_{p-1,p}^2)^2$. The off diagonal elements are given by

$$\text{cov}(r_{ij}, r_{kl}) = \rho_{ij}\rho_{kl} + \rho_{kl}\rho_{il} - \rho_{ij}(\rho_{ij}\rho_{kj} + \rho_{il}\rho_{kl}) - \rho_{kl}(\rho_{ij}\rho_{il} + \rho_{kj}\rho_{kl}) + \frac{1}{2}\rho_{kl}\rho_{ij}(\rho_{ij}^2 + \rho_{il}^2 + \rho_{kj}^2 + \rho_{kl}^2). \tag{5.4}$$

It may be noted that when $\rho_{ij} = 0$, $\Omega = I$, and thus $\sqrt{n}r \sim N_q(0, I)$ as $n \to \infty$. Since

$$\sum_{i<j}^p \rho_{ij}^2 = 0$$

if and only if $\rho_{ij} = 0$, a test for the hypothesis $H : \rho_{ij} = 0$ against the alternative $A : \rho_{ij} \neq 0$ for at least one pair of $(i, j), i \neq j$, can be based on the test statistic

$$T_3^* = \frac{n\sum_{i<j}^p r_{ij}^2 - q}{\sqrt{2q}}, \quad q = \frac{1}{2}p(p-1).$$

Since, under the hypothesis $H : \rho_{ij} = 0$, $nr_{ij}^2$ are asymptotically independently distributed with mean 1 and variance 2, it follows from the central limit theorem that as $p \to \infty$,

$$\sqrt{q} \left( n\sum_{i<j}^p r_{ij}^2 - \frac{q}{q} \right) \to N(0, 2).$$

Thus, asymptotically

$$\frac{n\sum_{i<j}^p r_{ij}^2 - q}{\sqrt{2q}} \to N(0, 1).$$

Thus, we get the following theorem
Theorem 5.1. Under the hypothesis $H : \rho_{ij} = 0$, asymptotically as $n$ and $p$ go to infinity

$$T_3^* \sim N(0, 1).$$

Under the alternative $A : \rho_{ij} = n^{-1/2}c_{ij}$, $-n^{1/2} < c_{ij} < n^{1/2}$, $\Omega = I + O(n^{-1/2})$. Hence, we get the following corollary.

Corollary 5.1. Under the alternative $\rho_{ij} = n^{-1/2}c_{ij}$, asymptotically

$$\left[ \frac{2q}{2(q + 2c'c)} \right]^{1/2} T_3^* \sim N \left( \frac{c'c}{\sqrt{2(q + 2c'c)}}, 1 \right).$$

The asymptotic normality of $T_3^*$ given in Theorem 5.1 is rather slow. Thus, as an alternative, Chen and Mudholkar (1990) considered the Fisher’s $z$-transformation $z_{ij}$, defined by

$$(5.5) \quad z_{ij} = \frac{1}{2} \log_e \frac{1 + r_{ij}}{1 - r_{ij}}$$

and proposed a test based on the test statistic

$$(5.6) \quad T_{3**} = (n - 2) \sum_{i<j}^p z_{ij}^2.$$ 

They approximated its distribution by a $X_v^2 + b$ where $v$, $a$ and $b$ are obtained by equating the first three moments of $T_{3**}^*$ with that of $aX_v^2 + b$ where $X_v^2$ is a chi-square random variable with $v$ degrees of freedom. However, neither of the two tests have been designed for large $p$. For example, the values of $a$, $v$, and $b$ depends only on $n$. Thus, we consider another parametric measure of the deviation of the hypothesis from the alternative and propose a test based on its consistent estimate. Let

$$(5.7) \quad a_{20} = \frac{1}{p} \sum_{i=1}^p \sigma_{ii}^2, \quad \hat{a}_{20} = \frac{n}{p(n + 2)} \sum_{i=1}^p s_{ii}^2$$

$$(5.8) \quad a_{40} = \frac{1}{p} \sum_{i=1}^p \sigma_{ii}^4, \quad \hat{a}_{40} = \frac{1}{p} \sum_{i=1}^p s_{ii}^4.$$ 

Then

$$a_2 = \frac{1}{p} \text{tr} \Sigma^2$$

$$= \frac{1}{p} \sum_{i=1}^p \sigma_{ii}^2 + \frac{1}{p} \sum_{i \neq j}^p \sigma_{ij}^2$$

$$= a_{20} + \frac{1}{p} \sum_{i \neq j}^p \sigma_{ij}^2.$$
We consider the parametric function

\[ \gamma_3 = \left( \frac{a_2}{a_{20}} \right). \]

Clearly \( \gamma_3 = 1 \) if and only if \( \sigma_{ij} = 0 \). And if \( \sigma_{ij} \neq 0, \gamma_3 \geq 1 \). Thus, we can base our test on a consistent estimator of \( \gamma_3 \) given by

\[ \hat{\gamma}_3 = \left( \frac{\hat{a}_2}{\hat{a}_{20}} \right) \]

where \( \hat{a}_2 \) is defined in (2.4), and \( \hat{a}_{20} \) is given in (5.7). We will be testing the hypothesis \( H : \gamma_3 - 1 = 0 \) against the alternative \( A : \gamma_3 - 1 \geq 0 \). Thus, it will also be a one-sided test.

We note that

\[ \hat{\gamma}_3 = \frac{n}{n-1} \frac{\sum_{i=1}^{p} s_{ii}^2 - \frac{1}{n} (\text{tr} S)^2}{\sum_{i=1}^{p} s_{ii}^2} = \frac{n}{n-1} \frac{\sum_{i \neq j} s_{ij}^2 + \sum_{i=1}^{p} s_{ii}^2 - \frac{1}{n} \sum_{i=1}^{p} s_{ii}^2 - \frac{1}{n} \sum_{i \neq j} s_{ii}s_{jj}}{\sum_{i=1}^{p} s_{ii}^2} = \frac{n}{n-1} \frac{\sum_{i \neq j} \left( s_{ij} - \frac{1}{n} s_{ii}s_{jj} \right)}{\sum_{i=1}^{p} s_{ii}^2} + 1, \]

which is a statistic based on the sample covariances and not on sample correlations. This appears to be a reasonable procedure as when \( n < p \), the sample covariance matrix \( S \) is singular, and in this case the diagonal elements \( s_{ii} \) may be very small and may lead to larger values of \( r_{ij} \). From the asymptotic theory given in Theorem 6.2, it follows that

\[ \hat{\gamma}_3 - 1 \to N \left[ \gamma_3 - 1, (a_{20})^{-1} \left( \frac{4}{n^2} \right) (a^2 - p^{-1}a_4) \right]. \]

Thus, we propose a test based on the test statistic

\[ T_3 = \left( \frac{n}{2} \right) \frac{(\hat{\gamma}_3 - 1)}{1 - \left( \frac{1}{p} \right) \left( \frac{a_{40}}{a_{20}^2} \right)}^{1/2}. \]

In the next theorem, we give an asymptotic distribution of \( T_3 \).

**Theorem 5.2.** Under the assumptions (A) and (B), the asymptotic distribution of \( T_3 \) is given by

\[ T_3 \sim N[\delta, \tau_3^2], \]
where
\[
\delta = \frac{n}{2} (\gamma_3 - 1) \left[ 1 - \left( \frac{1}{p} \right) \left( \frac{a_{40}}{a_{20}^2} \right) \right]^{-1/2}
\]
and
\[
\tau_3^2 = \frac{(a_2^2 - p^{-1}a_4)/(a_{20}^2 - p^{-1}a_{40})}{p}
\]
Since under the hypothesis $H$, $\delta = 0$, and $\tau_3^2 = 1$, we get the following corollary.

**Corollary 5.2.** Under the hypothesis $H : \sigma_{ij} = 0$, and under the assumptions (A) and (B), $T_3$ is asymptotically distributed as $N(0, 1)$.

### 6. Proofs

In this section, we prove lemmas and theorems stated in Sections 2 to 4. But before we begin these proofs, we state some results on the moments of a chi-square random variable with $n$ degrees of freedom, and other preliminary results.

#### 6.1. Preliminary results

We begin with the following lemma.

**Lemma 6.1.** Let $v$ be a chi-square random variable with $n$ degree of freedom. Then

\[
E(v^r) = n(n+2) \cdots (n+2r-2), \quad r = 1, 2, \ldots
\]
\[
\text{Var}(v) = 2n, \quad \text{Var}(v^2) = 8n(n+2)(n+3),
\]
\[
E(v - n)^3 = 8n, \quad E(v - n)^4 = 12n(n+4),
\]
\[
E[v^2 - n(n+2)]^4 = 3n(n+2)[272n^4 + O(n^3)].
\]

Next, we obtain expressions for $\text{tr} S$, $\text{tr} S^2$ and $(\text{tr} S)^2$ in terms of chi-square random variables. Let $V = nS = YY' \sim W_p(\Sigma, n)$, where $Y = (y_1, \ldots, y_n)$ and $y_i$ are iid $N_p(0, \Sigma)$. Let $\Gamma$ be an orthogonal matrix such that $\Gamma \Sigma \Gamma' = \Lambda$, where $\Lambda = \text{diag}(\lambda_1, \ldots, \lambda_p)$ and $\lambda_i$ are the eigenvalues of $\Sigma$. Then, if $U = (u_1, \ldots, u_n)$, where $u_i$ are iid $N_p(0, I)$, $Y = \Sigma^{1/2}U$, and $\Sigma^{1/2}\Sigma^{1/2} = \Sigma$,

\[
(\text{tr} S) = \frac{1}{n} \text{tr} U'\Sigma U = \frac{1}{n} \text{tr} W' \Lambda W = \frac{1}{n} \sum_{i=1}^p \lambda_i w_i'w_i,
\]
where $U'T' = W' = (w_1, \ldots, w_p)$, and $w_i$ are iid $N_n(0, I)$. Thus, if $v_{ii} = w'_iw_i$, $v_{ii}$ are iid chi-square random variables with $n$ degrees of freedom. Hence,

(6.1) $n\hat{\alpha}_1 = n(\text{tr } S) = \sum_{i=1}^{p} \lambda_{i}v_{ii},$

(6.2) $n^2(\text{tr } S)^2 = \left[ \sum_{i=1}^{p} \lambda_{i}^2v_{ii}^2 + 2 \sum_{i<j}^{p} \lambda_{i}\lambda_{j}v_{ij}v_{jj} \right],$

and

(6.3) $n^2 \text{tr } S^2 = \text{tr}(W' \wedge W)(W' \wedge W) = \text{tr} \left[ \left( \sum_{i=1}^{p} \lambda_{i}w_iw'_i \right) \left( \sum_{i=1}^{p} \lambda_{i}w_iw'_i \right) \right]$

$= \text{tr} \left[ \sum_{i=1}^{p} \lambda_{i}^2w_iw'_iw'_iw_i + 2 \sum_{i<j}^{p} \lambda_{i}\lambda_{j}w_iw'_iw_jw'_j \right]$

$= \left[ \sum_{i=1}^{p} \lambda_{i}^2(w'_iw_i)^2 + 2 \sum_{i<j}^{p} \lambda_{i}\lambda_{j}(w'_iw_j)^2 \right]$

$= \sum_{i=1}^{p} \lambda_{i}^2v_{ii}^2 + 2 \sum_{i<j}^{p} \lambda_{i}\lambda_{j}v_{ij}^2,$

where

(6.4) $v_{ij} = w'_iw_j, \quad i \neq j, \quad v_{ii} = w'_iw_i.$

Thus, since $n^2/(n-1)(n+2) \simeq 1,$

(6.5) $\hat{\alpha}_2 \simeq \frac{1}{p} \left[ \text{tr } S^2 - \frac{1}{n}(\text{tr } S)^2 \right]$

$= \frac{1}{n^2p} \left[ \sum_{i=1}^{p} \lambda_{i}^2v_{ii}^2 + 2 \sum_{i<j}^{p} \lambda_{i}\lambda_{j}v_{ij}^2 - \frac{1}{n} \left( \sum_{i=1}^{p} \lambda_{i}^2v_{ii}^2 + 2 \sum_{i<j}^{p} \lambda_{i}\lambda_{j}v_{ii}v_{jj} \right) \right]$

$= \frac{1}{n^2p} \left[ \frac{n-1}{n} \sum_{i=1}^{p} \lambda_{i}^2v_{ii}^2 + 2 \sum_{i<j}^{p} \lambda_{i}\lambda_{j} \left( v_{ij}^2 - \frac{1}{n}v_{ii}v_{jj} \right) \right]$

$= \left[ \frac{n-1}{n^3p} \sum_{i=1}^{p} \lambda_{i}^2v_{ii}^2 \right] + \left[ \frac{2}{n^2p} \sum_{i<j}^{p} \lambda_{i}\lambda_{j}z_{ij} \right]$

$= q_1 + q_2,$

where

(6.6) $z_{ij} = v_{ij}^2 - \frac{1}{n}v_{ii}v_{jj}$

$= (w'_iw_j)^2 - \frac{1}{n}(w'_iw_i)(w'_jw_j).$
From now on, we shall consider only the asymptotic version of $\hat{a}_2$, without the sign '$\approx$'.

**Lemma 6.2.** For $z_{ij}$ defined above, we have

$$E(z_{ij}) = 0, \quad E(z_{ij}z_{ik}) = 0, \quad \text{for all distinct } i, j, k,$$

(6.7) \quad \text{Var}(z_{ij}) = 2(n + 2)(n - 1).

**Proof.** Since $w_i$ are iid $N_n(0, I_n)$, it follows that

$$E(z_{ij}) = E \left[ w_i' w_j' w_i - \frac{1}{n} (w_i' w_j)(w_j' w_i) \right]$$

$$= E(w_i' w_i) - \frac{1}{n} \times n \times n$$

$$= 0,$$

as $E(w_j w_j') = I_n$ and $E(w_i' w_i) = n$.

Similarly, for all distinct $i$, $j$, $k$,

$$E[z_{ij} z_{ik}] = E \left[ (w_j' w_i)^2 - \frac{1}{n} (w_i' w_i)(w_j' w_j) \right] \left[ (w_k' w_i)^2 - \frac{1}{n} (w_i' w_i)(w_k' w_k) \right]$$

$$= E \left[ (w_j' w_i)^2 (w_k' w_i)^2 - \frac{1}{n} (w_k' w_i)^2 (w_i' w_i)(w_j' w_j) \right.$$\n
$$- \frac{1}{n} (w_j' w_i)^2 (w_i' w_i)(w_k' w_k) + \frac{1}{n^2} (w_i' w_i)^2 (w_j' w_j)(w_k' w_k) \right].$$

Thus,

$$E[(w_j' w_i)^2 (w_k' w_i)^2] = E[(w_j' w_i w_j')(w_i' w_k w_k' w_i)]$$

$$= E[\{w_i', (w_j' w_j')(w_i')\} \{w_i', (w_k' w_k')(w_i')\}]$$

$$= E[(w_i' w_i)(w_i' w_i)]$$

$$= n(n + 2),$$

$$E[(w_i' w_i)(w_j' w_j)(w_k' w_k') w_i)] = E[(w_i' w_i)(w_j' w_j)(w_i' w_i)]$$

$$= n^2(n + 2),$$

$$E[(w_i' w_i)(w_i' w_i)(w_j' w_j)(w_i') w_i)] = nE[(w_i' w_i)^2 (w_k' w_k)]$$

$$= n^2(n + 2),$$

and,

$$E[(w_i' w_i)^2 (w_j' w_j)(w_k' w_k)] = n^3(n + 2).$$

Hence, for all distinct $i$, $j$, $k$

$$E[z_{ij} z_{ik}] = 0.$$

To calculate the variance of $z_{ij}$, we note that

$$z_{ij} = v_{ij}^4 - \frac{2}{n} v_{ij} v_{ij} v_{jj} + \frac{1}{n^2} v_{ii}^2 v_{jj}^2, \quad i \neq j,$$

and
\[ E(v_{ij}^4) = E(w_i'w_jw_j'w_i)^2 = E(w_i'A_jw_i)^2, \]

where \( A_j = w_jw_j' \). Let \( G \) be an orthogonal matrix such that \( GA_jG' = \text{diag}(w_j'w_j, 0, \ldots, 0) \). Since given \( A_j, l_i = Gw_i \sim N_n(0, I) \), it follows that \( l_i \) is independently distributed of \( A_j \), and

\[ E(v_{ij}^4) = E[z_{ij}^4(w_j'w_j)^2] = 3n(n + 2), \]

where \( l_i = (l_{1i}, \ldots, l_{ni})' = Gw_i \sim N_n(0, I) \). Thus, \( l_i \sim N(0, 1) \) and is independently distributed of \( w_j'w_j \). Similarly,

\[ E(v_{ij}^2v_{ii}v_{jj}) = E(w_i'w_jw_j'w_i)(w_i'w_i)(w_j'w_j) = E(w_i'A_jw_i)(w_i'w_i)(tr A_j), \quad A_j = w_jw_j' \]

\[ = E \left[ l_{1i}^2w_j'w_j \left( \sum_{k=1}^n l_{ki}^2 \right) (w_j'w_j) \right] = E(w_j'w_j)^2E \left( l_{1i}^2 \sum_{k=1}^n l_{ki}^2 \right) = n(n + 2)(n + 2) = n(n + 2)^2. \]

Finally,

\[ E(v_{ii}^2v_{jj}^2) = n^2(n + 2)^2. \]

Hence,

\[ \text{Var}(z_{ij}) = 3n(n + 2) - 2(n + 2)^2 + (n + 2)^2 = 3n(n + 2) - (n + 2)^2 = 2(n + 2)(n - 1). \]

**Lemma 6.3.** Let \( v_{ii} \) be iid as \( \chi^2_n \),

\[ q_1 = \frac{n - 1}{n^3p} \sum_{i=1}^p \lambda_i^2 v_{ii}, \quad \text{and} \quad q_2 = \frac{2}{n^2p} \sum_{i<j}^p \lambda_i\lambda_j z_{ij}. \]

Then,

\[ \text{Cov}(q_1, q_2) = 0 \]

\[ \text{Var}(q_1) = \left[ 8(n + 2)(n + 3)(n - 1)^2/pn^5 \right] a_4 \]

\[ \text{Var}(q_2) = \left[ 8(n + 2)(n - 1)/n^4 \right] \left[ \sum_{i<j}^p \lambda_i^2\lambda_j^2/p^2 \right] \]

\[ \simeq (4/n^2)[a_2^2 - (a_4/p)]. \]
**Proof.** Since $E(q_2) = 0$, we get

$$\left( \frac{n^5 p^2}{2(n - 1)} \right) \text{Cov}(q_1, q_2) = \left( \frac{n^5 p^2}{2(n - 1)} \right) E(q_1 q_2)$$

$$= E \left[ \sum_{i=1}^{p} \lambda_i^2 v_{ii}^2 \right] \left[ \sum_{j<k} \lambda_j \lambda_k z_{jk} \right]$$

$$= \lambda_1^2 E \left( v_{11}^2 \right) \left[ \sum_{j<k} \lambda_j \lambda_k z_{jk} \right]$$

$$+ \lambda_2^2 E \left( v_{22}^2 \right) \left[ \sum_{j<k} \lambda_j \lambda_k z_{jk} \right]$$

$$+ \cdots + \lambda_p^2 E \left( v_{pp}^2 \right) \left[ \sum_{j<k} \lambda_j \lambda_k z_{jk} \right].$$

We note that

$$E[v_{ii}^2 z_{jk}, j \neq k]$$

$$= E \left[ (w_i' w_i)^2 \left\{ (w_j' w_k)^2 - \frac{1}{n} (w_j' w_j) (w_k' w_k) \right\} \right]$$

$$= E \left[ (w_i' w_i)^2 (w_j' w_k w_k' w_j) - \frac{1}{n} (w_i' w_i)^2 (w_j' w_j) (w_k' w_k) \right]$$

$$= E \left[ (w_i' w_i)^3 - \frac{1}{n} (w_i' w_i)^3 (w_k' w_k) \right] = 0, \quad i = j \neq k$$

$$= E \left[ (w_i' w_i)^2 (w_j' w_j) - \frac{1}{n} (w_i' w_i)^2 (w_j' w_j) (w_k' w_k) \right] = 0, \quad i \neq j \neq k$$

$$= E \left[ (w_i' w_i)^2 (w_j' w_j) - \frac{1}{n} (w_i' w_i)^3 (w_j' w_j) \right] = 0, \quad j \neq k = i.$$

The variances of $q_1$ and $q_2$ can easily be obtained.

Note that,

$$(6.12) \quad 2p^{-2} \sum_{i<j} \lambda_i^2 \lambda_j^2 = p^{-2} \left[ \left( \sum_{i=1}^{p} \lambda_i^2 \right)^2 - \sum_{i=1}^{p} \lambda_i^4 \right]$$

$$= \left( \frac{\sum \lambda_i^2}{p} \right)^2 - \frac{1}{p} \left( \sum_{i=1}^{4} \lambda_i^4 \right)$$

$$= a_2^2 - (a_4/p),$$

which is bonded under the assumption (A). Hence, we get the following corollary.
Corollary 6.1. As $n \to \infty$, $q_2 \to 0$ in probability under the assumption (A). Thus, also under the assumptions (A) and (B), $q_2 \to 0$ in probability as $p \to \infty$.

Corollary 6.2. Let

$$\hat{a}_1 = \frac{1}{pn} \left( \sum_{i=1}^{p} \lambda_i v_{ii} \right) = \left( \frac{\text{tr} \ S}{p} \right).$$

Then

$$\text{Cov}(q_2, \hat{a}_1) = 0.$$ 

Lemma 6.4. Let $nS \sim W_p(\Sigma, n)$, and

$$\hat{a}_2 = \frac{1}{p} \left[ \text{tr} \ S^2 - \frac{1}{n} \left( \text{tr} \ S \right)^2 \right] = q_1 + q_2.$$

Then, from (6.10), and (6.11) and the fact that $\text{Cov}(q_1, q_2) = 0$,

$$\text{Var}(\hat{a}_2) = \text{Var}(q_1) + \text{Var}(q_2)$$

$$= \frac{8(n+2)(n+3)(n-1)^2}{pn^5} a_4 + \frac{4(n+2)(n-1)}{n^4} [a_2^2 - p^{-1} a_4]$$

$$\approx \frac{8a_4}{pn} + \frac{4}{n^2} [a_2^2 - p^{-1} a_4]$$

$$\approx \frac{4}{n^2} \left[ a_2^2 + \frac{2n}{p} a_4 \right].$$

Lemma 6.5. Let $v_{ii}$ be iid as $\chi^2_n$, $q_1 = (n-1)(pn^{-3})^{-1} \sum_{i=1}^{p} \lambda_i^2 v_{ii}^2$, and $\hat{a}_1 = (pn)^{-1} \sum_{i=1}^{p} \lambda_i v_{ii}$. Then

$$\text{Cov}(q_1, \hat{a}_1) = 4(n-1)(n+2)a_3/pn^3 \approx 4a_3/(pn) \quad \text{as} \quad n \to \infty.$$

Proof. We have

$$\frac{p^2 n^4}{(n-1)} \text{Cov}(q_1, \hat{a}_1)$$

$$= \left[ E \left( \sum_{i=1}^{p} \lambda_i^2 v_{ii}^2 \right) \left( \sum_{i=1}^{p} \lambda_i v_{ii} \right) - n^2(n+2)p^2 a_2 a_1 \right]$$

$$= \left[ E \left( \sum_{i=1}^{p} \lambda_i^2 v_{ii}^3 + \sum_{i \neq j} \lambda_i^2 v_{ii}^2 \lambda_j v_{jj} \right) - n^2(n+2)p^2 a_2 a_1 \right]$$

$$= \left[ n(n+2)(n+4)pa_3 + n^2(n+2) \sum_{i \neq j} \lambda_i^2 \lambda_j - n^2(n+2)p^2 a_2 a_1 \right]$$

$$= \left[ 4n(n+2)pa_3 \right].$$
Next, we obtain the variance of $\hat{\gamma}_2$. We have

\begin{equation}
\hat{\gamma}_2 \simeq \frac{1}{p} \left[ \text{tr} S^2 - \frac{1}{n} (\text{tr} S)^2 - 2 \text{tr} S \right]
\end{equation}

\begin{align*}
&= \frac{1}{p} \left( \frac{n-1}{n^2} \sum \lambda_i^2 v_{ii}^2 + \frac{2}{pn^2} \sum_{i<j} W_{ij} - \frac{2}{pn} \sum \lambda_i v_{ii} \right) \\
&\simeq \frac{1}{pn^2} \sum \lambda_i^2 v_{ii}^2 - \frac{2}{pn} \sum \lambda_i v_{ii} + \frac{2}{pn^2} \sum_{i<j} W_{ij} \\
&= \frac{1}{pn^2} \sum \left[ \lambda_i^2 v_{ii}^2 - 2nv_{ii} \lambda_i \right] + \frac{2}{pn^2} \sum_{i<j} W_{ij},
\end{align*}

where

\begin{equation}
W_{ij} = \lambda_i \lambda_j z_{ij}.
\end{equation}

Now

\begin{equation}
\text{Var}[\lambda_i^2 v_{ii}^2 - 2nv_{ii} \lambda_i]
\end{equation}

\begin{align*}
&= \lambda_i^4 \text{Var}(v_{ii}^2) - 4n\lambda_i^3 \text{Cov}(v_{ii}^2, v_{ii}) + 4n^2 \lambda_i^2 \text{Var}(v_{ii}) \\
&= 8n(n+2)(n+3)\lambda_i^4 + 8n^3 \lambda_i^2 - 4n\lambda_i^3 E[(v_{ii} - n)v_{ii}^2] \\
&= 8n(n+2)(n+3)\lambda_i^4 + 8n^3 \lambda_i^2 - 4n\lambda_i^3 E[v_{ii}^3 - nv_{ii}^2] \\
&= 8n(n+2)(n+3)\lambda_i^4 + 8n^3 \lambda_i^2 \\
&- 4n\lambda_i^3 [n(n+2)(n+4) - n^2(n+2)] \\
&= 8n(n+2)(n+3)\lambda_i^4 + 8n^3 \lambda_i^2 - 16n^2(n+2)\lambda_i^3.
\end{align*}

Hence,

\begin{align*}
\text{Var} \left[ \frac{1}{p} \left( \text{tr} S^2 - \frac{1}{n} (\text{tr} S)^2 - 2 \text{tr} S \right) \right]
&\simeq \text{Var} \left[ \frac{1}{pn^2} \left( \sum \lambda_i^2 v_{ii}^2 - 2nv_{ii} \lambda_i \right) \right] + \text{Var} \left[ \frac{2}{pn^2} \sum_{i<j} W_{ij} \right] \\
&+ 2 \text{Cov} \left[ \frac{1}{pn^2} \left( \sum_{i=1}^{p} \lambda_i^2 v_{ii}^2 - 2nv_{ii} \lambda_i \right), \frac{2}{pn^2} \sum_{i<j} W_{ij} \right] \\
&= 8n(n+2)(n+3)\lambda_i^4 + 8n^3 \lambda_i^2 - 16n^2(n+2)\lambda_i^3 \\
&+ \frac{4(n+2)(n-1)\lambda_i^2 \lambda_j^2}{n^4 p^2} + 0 \\
&= 8n(n+2)(n+3)\lambda_i^4 + 8n^3 a_2 - 16n^2(n+2)\lambda_i^3 \\
&+ \frac{4(n+2)(n-1)\lambda_i^2 \lambda_j^2}{n^4 p} \\
&\simeq 8a_4 + 8a_2 - 16a_3 + \frac{4}{n^2} \left[ a_2 - \frac{1}{p} a_4 \right].
\end{align*}
Hence, we get the following lemma

**Lemma 6.6.** For $\hat{\gamma}_2$ defined above,

$$\text{Var}(\hat{\gamma}_2) \simeq \frac{8a_4 - 16a_3 + 8a_2}{np} + \frac{4}{n^2}[a_2^2 - p^{-1}a_4].$$

**Corollary 6.3.** When $\lambda_i = 1$,

$$\text{Var}(\hat{\gamma}_2) \simeq \frac{4}{n^2}, \quad \text{for large } n \text{ and } p.$$

Let

$$u_{1i} = \frac{\lambda_i(v_{ii} - n)}{\sqrt{n}}, \quad u_{2i} = \frac{\lambda_i^2[v_{ii}^2 - n(n + 2)]}{\sqrt{n(n + 2)(n + 3)}},$$

and

$$\varepsilon_n = [(n + 2)/(n + 3)]^{1/2}.$$

Then

$$E(u_{1i}) = 0, \quad E(u_{2i}) = 0,$$

$$\text{Var}(u_{1i}) = 2\lambda_i^2, \quad \text{Var}(u_{2i}) = 8\lambda_i^4,$$

$$\text{Cov}(u_{1i}, u_{2i}) = 4\varepsilon_n\lambda_i^3.$$

Thus $u_i = (u_{1i}, u_{2i})$ are independently distributed random vectors, $i = 1, \ldots, p$, with mean vectors as zero vectors and the $2 \times 2$ covariance matrices $M_{in}$ given by

$$M_{in} = \begin{pmatrix} 2\lambda_i^2 & 4\varepsilon_n \lambda_i^3 \\ 4\varepsilon_n \lambda_i^3 & 8\lambda_i^4 \end{pmatrix}, \quad i = 1, \ldots, p.$$

Now, as $p \to \infty$

$$M_n \equiv \frac{1}{p}(M_{1n} + \ldots + M_{pn})$$

$$= \begin{pmatrix} 2a_2 & 4\varepsilon_n a_3 \\ 4\varepsilon_n a_3 & 8a_4 \end{pmatrix} \to M_n^0 \neq 0, \quad \text{for any } n,$$

where

$$M_n^0 = \begin{pmatrix} 2a_2^0 & 4\varepsilon_n a_3^0 \\ 4\varepsilon_n a_3^0 & 8a_4^0 \end{pmatrix} \to \begin{pmatrix} 2a_2^0 & 4a_3^0 \\ 4a_3^0 & 8a_4^0 \end{pmatrix} \equiv M^0 \quad \text{as } n \to \infty.$$
Also, if $F_i$ is the distribution function of $u_i$, then
\[
\frac{1}{p} \sum_{i=1}^{p} \int_{(u'u) > p\varepsilon^2} u'u dF_i \leq \frac{1}{p} \sum_{i=1}^{p} (p\varepsilon^2)^{-1} \int (u'u)^2 dF_i
\]
\[
= \frac{1}{p^2\varepsilon^2} \sum_{i=1}^{p} E(u_{1i}^2 + u_{2i}^2)
\]
\[
\leq \frac{2}{p^2\varepsilon^2} \sum_{i=1}^{p} E(u_{1i}^4 + u_{2i}^4),
\]
from $c_r$-inequality, see Rao (1973, p. 149). Now
\[
\frac{1}{p^2} \sum_{i=1}^{p} E(u_{1i}^4) = \frac{1}{p^2} \sum_{i=1}^{p} \lambda_i^4 E(v_i - n)^4
\]
\[
= \frac{12n(n+4)a_4}{n^2} \frac{1}{p} \to 0 \quad \text{as} \quad p \to \infty.
\]
Similarly
\[
\frac{1}{p^2} \sum_{i=1}^{p} E(u_{2i}^4) = \frac{1}{p^2} \sum_{i=1}^{p} \lambda_i^8 \frac{E(v_i^2 - n(n+2))^4}{n^2(n+2)^2(n+3)^2}
\]
\[
= O(p^{-1}) \to 0 \quad \text{as} \quad p \to \infty.
\]
Then from the multivariate central limit theorem of Liapunov type given in Rao (1973, p. 147, Problem 4.7), it follows that as $p \to \infty$, and for any $n$,
\[
\frac{1}{\sqrt{p}} \sum_{i=1}^{p} u_i = \frac{1}{\sqrt{np}} \left( \sum_{i=1}^{p} \lambda_i (v_{ii} - n) \right) \sim N_2(0, M_n^0).
\]
Thus, it follows that as $p \to \infty$ and then $n \to \infty$,
\[
\frac{1}{p} \sum_{i=1}^{p} u_i \to N_2(0, M^0).
\]
On the otherhand, as $n \to \infty$, we get from the multivariate central limit theorem that
\[
u_i \to N_2(O, M_i), \quad i = 1, \ldots, p
\]
for any $p$, where $M_i$ is the limit of $M_{in}$ given by
\[
(6.22) \quad M_i = \begin{pmatrix}
2\lambda_i^2 & 4\lambda_i^3 \\
4\lambda_i^3 & 8\lambda_i^4
\end{pmatrix}.
\]
Let
\[
(6.23) \quad M = \frac{1}{p} (M_1 + \ldots + M_p) = \begin{pmatrix}
2a_2 & 4a_3 \\
4a_3 & 8a_4
\end{pmatrix},
\]
which goes to $M^0$ as $p \to \infty$. Since $u_i$ are asymptotically independently distributed, it follows from the argument given above that as $n \to \infty$, and then $p \to \infty$

$$\frac{1}{\sqrt{p}} \sum_{i=1}^{p} u_i \to N_2(0, M^0).$$

Without any loss of generality, we may replace $M^0$ by $M$. Noting that

$$\hat{a}_1 = (np)^{-1} \sum_{i=1}^{p} \lambda_i v_{ii},$$

and

$$q_1 = \frac{n-1}{n^3 p} \sum_{i=1}^{p} \lambda_i^2 v_{ii}^2$$

$$\simeq \frac{1}{n^2 p} \sum_{i=1}^{p} \lambda_i^2 v_{ii}^2$$

we get the following theorem

**Theorem 6.1.** As $n$ and $p \to \infty$, in any manner,

$$\begin{pmatrix} \hat{a}_1 \\ q_1 \end{pmatrix} \to N_2 \left[ \begin{pmatrix} a_1 \\ a_2 \end{pmatrix}, (np)^{-1} M \right].$$

**Corollary 6.4.** For any finite $n$, and as $p \to \infty$,

$$\begin{pmatrix} \hat{a}_1 \\ q_1 \end{pmatrix} \to N_2 \left[ \begin{pmatrix} a_1 \\ a_2 \end{pmatrix}, (np)^{-1} M_n \right].$$

**Theorem 6.2.** Let $z_{ij}$ be as defined in (6.6), and

$$q_2 = \frac{2}{n^2 p} \sum_{i<j} \lambda_i \lambda_j z_{ij}.$$ 

Then under the assumptions (A) and (B), and as $n$ and $p \to \infty$, $q_2 \sim N[0, 4n^{-2}(a_2^2 - p^{-1}a_4)].$

**Proof.** Note that

$$z_{ij} = (w_i'w_j)^2 - \frac{1}{n}(w_i'w_i)(w_j'w_j)$$

$$= v_{ij}^2 - \frac{1}{n} v_{ii} v_{jj},$$

and

$$n^{-1} z_{ij} = (n^{-1} v_{ij}^2 - 1) - n^{-2}(v_{ii} v_{jj} - n^2).$$
The second term goes to zero in probability and Cov\left[n^{-1}(v_{ij} - n), n^{-1}(v_{ik} - n)\right] \to 0 as \( n \to \infty \) for all distinct \( i, j, k \). Since \( n^{-1/2}v_{ij} \sim N(0,1) \) as \( n \to \infty \), it follows that \( n^{-1}v_{ij}^2 \) is a chi-square random variable with one degree of freedom and are asymptotically independently distributed for all distinct \( i \) and \( j \). Now, when \( p \to \infty \), we apply Liapunov type central limit theorem to obtain the asymptotic normality of \( q_2 \). Because of the normality assumption, the same result is obtained if we interchange the order of limit.

Next, we note that Cov\((\hat{a}_1, q_2) = 0 \) and Cov\((q_1, q_2) = 0 \). From the asymptotic normality of \((\hat{a}_1, q_1)\) and the fact that the covariance between \((\hat{a}_1, q_1)\) and \(q_2\) is a zero vector, it follows that \((\hat{a}_1, q_1, q_2)\) are jointly asymptotically normally distributed as stated in the following theorem.

**THEOREM 6.3.** Under the assumptions (A) and (B), asymptotically

\[
\begin{pmatrix}
\hat{a}_1 \\
q_1 \\
q_2
\end{pmatrix}
\sim N
\begin{pmatrix}
a_1 \\
a_2 \\
0
\end{pmatrix},
\begin{pmatrix}
\frac{1}{np}M & 0 \\
0 & 4n^{-2}(a_2^2 - p^{-1}a_4)
\end{pmatrix}.
\]

**6.2. Proof of Lemma 2.1**

From (6.5), and Lemma 6.2

\[
E(\hat{a}_2) = \frac{1}{p}E\left[ \text{tr} S^2 - \frac{1}{n}(\text{tr} S)^2 \right]
\]

\[
= \frac{n-1}{n^3p}E \left[ \sum_{i=1}^p \lambda_i^2 v_i^2 \right] + \frac{2}{n^2p}E \left[ \sum_{i<j} \lambda_i \lambda_j z_{ij} \right]
\]

\[
= \frac{n-1}{n^3p}n(n+2) \sum_{i=1}^p \lambda_i^2 + \frac{2}{n^2p} \sum_{i<j} \lambda_i \lambda_j E(z_{ij})
\]

\[
= \frac{(n-1)(n+2)}{n^2} \left( \frac{\text{tr} \Sigma^2}{p} \right).
\]

Hence,

\[
(6.24)
\]

\[
\frac{n^2}{(n-1)(n+2)} \frac{1}{p} \left[ \text{tr} S^2 - \frac{1}{n}(\text{tr} S)^2 \right]
\]

is an unbiased estimator of \((\text{tr} \Sigma^2/p)\).

From Lemma 6.3, \( q_2 \) goes to zero in probability as \( n \to \infty \). Thus it follows from Lemma 6.4 and equation (6.5) that (6.12) is under assumption (A), an unbiased and consistent estimator of \( a_2 \) as \( n \to \infty \), and

\[
\hat{a}_2 = \frac{1}{p} \left[ \text{tr} S^2 - \frac{1}{n}(\text{tr} S)^2 \right]
\]

is a consistent estimator of \( a_2 \) as \( n \) goes to infinity and the assumption (A) holds.
6.3. Proof of Theorem 2.1 and Corollary 2.1
Since \( \hat{a}_2 = q_1 + q_2 \) and \( \hat{a}_1 = [\sum_{i=1}^{p} \lambda_i v_i / pn] = (\text{tr} S / p) \), it follows from Theorem 6.3 that

\[
\begin{pmatrix}
\hat{a}_1 \\
\hat{a}_2
\end{pmatrix}
\sim
N_2\left[
\begin{pmatrix}
a_1 \\
a_2
\end{pmatrix},
(np)^{-1}
\begin{pmatrix}
2a_2 & 4a_3 \\
4a_3 & 8a_4 + 4\frac{p}{n}a_2^2
\end{pmatrix}
\right].
\]

To prove Corollary 2.1, we note that \( c = p/n \),

\[
g_1(\hat{a}_1, \hat{a}_2) \equiv \frac{1}{p} (\text{tr} S) = \hat{a}_1,
\]

and

\[
g_2(\hat{a}_1, \hat{a}_2) \equiv \frac{1}{p} (\text{tr} S^2) = \hat{a}_2 + c\hat{a}_1^2.
\]

Hence, from Lemma 2.3, the covariance of \((g_1, g_2)\) is given by

\[
(np)^{-1}\begin{pmatrix}
d\partial q_1 / d\hat{a}_1 & d\partial q_1 / d\hat{a}_2 \\
d\partial q_2 / d\hat{a}_1 & d\partial q_2 / d\hat{a}_2
\end{pmatrix}
\begin{pmatrix}
2a_2 & 4a_3 \\
4a_3 & 8a_4 + 4ca_2^2
\end{pmatrix}'
\begin{pmatrix}
d\partial q_1 / d\hat{a}_1 & d\partial q_1 / d\hat{a}_2 \\
d\partial q_2 / d\hat{a}_1 & d\partial q_2 / d\hat{a}_2
\end{pmatrix}^{-1}
\]

\[
= (np)^{-1} \begin{pmatrix}
1 & 0 \\
2a_1c & 1
\end{pmatrix}
\begin{pmatrix}
2a_2 & 4a_3 \\
4a_3 & 8a_4 + 4ca_2^2
\end{pmatrix}
\begin{pmatrix}
1 & 2a_1c \\
0 & 1
\end{pmatrix}
\]

\[
= n^{-2}c^{-1} \begin{pmatrix}
2a_2 & 4(ca_1a_2 + a_3) \\
4(ca_1a_2 + a_3) & 4(2c^2a_2^2a_2 + 4ca_1a_3 + ca_2^2 + 2a_4)
\end{pmatrix}.
\]

6.4. Proof of Theorem 3.1
We note that

\[
T_1 = \frac{\hat{a}_2}{\hat{a}_1^3} - 1.
\]

Hence,

\[
\frac{\partial T_1}{\partial \hat{a}_1} = -2\frac{\hat{a}_2}{\hat{a}_1^3}, \quad \text{and} \quad \frac{\partial T_1}{\partial \hat{a}_2} = \frac{1}{\hat{a}_1^3}.
\]

Thus, asymptotically,

\[
T_1 \sim N(\gamma_1 - 1, \tau_1^2)
\]

where

\[
\tau_1^2 = \left( \frac{2a_2}{a_1^3}, 1 \right) \left( \frac{2a_2}{n p}, \frac{4a_3}{n p} \right) \left( \frac{4a_3}{n p}, \frac{8a_4}{n p} + 4a_2^2/n^2 \right) \left( \frac{2a_2}{a_1^3} \right)
\]

\[
= \left[ -\frac{4a_2}{n p a_1^3} + \frac{4a_3}{n p a_1^3} - \frac{8a_2a_3}{n p a_1^3} + \frac{1}{a_1^3} - \frac{8a_4}{n p} + 4a_2^2/n^2 \right] \left( \frac{2a_2}{a_1^3} \right)
\]

\[
= \frac{8a_2^3}{n p a_1^6} - \frac{16a_2a_3}{n p a_1^5} + \frac{1}{a_1^4} \left( \frac{8a_4}{n p} + 4a_2^2/n^2 \right)
\]

\[
= \frac{8a_2^3}{n p a_1^6} - \frac{16a_2a_3}{n p a_1^5} + \frac{8a_4}{n p a_1^4} + \frac{4a_2^2}{n^2 a_1^4}.
\]

Thus, when \( \lambda_i = \lambda \),

\[
\tau_1^2 = 4/n^2.
\]
6.5. Proof of Theorem 4.1

Since
\[ \hat{\gamma}_2 = \hat{a}_2 - 2\hat{a}_1 \]
it follows from Theorem 6.3 that asymptotically
\[ T_2 \sim N(\gamma_2 + 1, \tau_2^2) \]
where
\[ \tau_2^2 = \frac{8a_4 - 16a_3 + 8a_2 + 4a_2^2}{np} + \frac{4a_2}{n^2}. \]

Thus, when \( \lambda_i = 1 \),
\[ \tau_2^2 = \frac{4}{n^2}. \]
